2 Structure

The configuration for the default implementation is:

3 Message format

- Valid characters are 0-9
- Message length must be 7 or 8 characters depending on the checksum mode.
- Behaviour when checksum-mode is set to auto: If a 7-character message is passed in, the check character is added. If a 8-character message is passed in, the check character is checked.
- The first character (number system) must be 0 or 1.
- You can pass in a UPC-A message (12 or 13 characters) to generate a UPC-E barcode. If the UPC-A
 message cannot be converted to a UPC-E message you'll get an exception.
- Supplementals are supported (2 and 5 characters). You can add them by appending a "+" along with the supplemental message to the barcode message. Example: 0123413+77
